Subsistence harvest of bowhead whales (Balaena mysticetus) by
Alaskan Eskimos during 2012

ABSTRACT

In 2012, 69 bowhead whales (Balaena mysticetus) were struck during the Alaskan subsistence
hunt resulting in 55 animals landed. Total number of whales landed in 2012 was higher than the
average for the previous 10 years (2002-2011: mean of landed = 38.9; SD = 7.1) as was the
number struck (2002-201: mean struck = 51.4; SD = 12.1). The efficiency (# landed / # struck) of
the hunt (0.80%) was similar to the past 10 years (mean of efficiency = 77%; SD = 0.07%). Total
mortality for 2012 was estimated at 66 animals after the estimated fate of the struck and lost
whales was considered. Spring hunts are logistically and environmentally more difficult than
autumn hunts because of severe environmental conditions and sea ice dynamics. Typically, hunt
efficiency during spring is lower than autumn. In 2012, the efficiency of the spring hunt (71%)
was lower than the autumn hunt (100%). This was due in part to difficult environmental
conditions during spring and that struck whales were lost under ice. Of the landed whales, 29
were females, 24 were males, and sex was not determined for two animals. Based on total length,
six of the 29 females were presumed mature (>13.4 m in length). All five (100%) of the mature
females that were examined were pregnant.

WHALING-ABORIGINAL

INTRODUCTION

The subsistence harvest of bowhead whales (Balaena mysticetus) meets an important nutritional and
cultural need for several Native communities in northern and western Alaska (United States) and eastern
Chukotka (Russia). The Alaska Eskimo Whaling Commission (AEWC), comprised of 11 communities,
locally manages the Alaskan harvest through an agreement with the U.S. National Oceanic and
Atmospheric Administration (NOAA). The level of allowable harvest is determined under a quota system
in compliance with the International Whaling Commission (IWC, 1980; Gambell, 1982). The quota is
based on the nutritional and cultural needs of Alaskan Eskimos as well as on estimates of the size and
growth of the Bering-Chukchi-Beaufort seas stock of bowhead whales (Donovan, 1982; Braund, 1992).
Whales were harvested in 2012 under a five-year block quota that began in 2008 (IWC, 2008).

The subsistence hunt typically occurs during spring and autumn as whales generally migrate between the
Bering and Beaufort seas. Hunters on St. Lawrence Island in the northern Bering Sea may harvest whales
during the winter (i.e., December and January) as well. Bowhead harvests are subjected to considerable
environmental interference from weather (wind speed and direction, fog, and temperature), stability of
landfast ice, and sea ice concentration and type. The success of each hunt is greatly affected by these
factors and shows considerable annual and regional variation.
Since 1981, the North Slope Borough Department of Wildlife Management has gathered basic data on landed whales in several communities, especially Barrow. Additionally, with assistance from the UAF-Marine Advisory Program and previously with the Alaska Department of Fish and Game, we have collected detailed information and tissue samples from harvested whales landed at Kaktovik, Gambell and Savoonga on Saint Lawrence Island, and other villages in recent years. We assisted the AEWC in compiling statistics on landed and struck and lost whales (Albert, 1988). The objectives of this paper were to document: (1) the number, location (village), and dates of landed and struck-and-lost bowhead whales during 2012 in Alaska, (2) the estimated fate of struck and lost bowhead whales, (3) basic morphometric data and the sex composition of the harvest, (4) the hunting efficiency of the harvest, and (5) relevant additional observations (hunting conditions, unusual pathology, etc.).

METHODS

Harvest data on sex, standard length, harvest and landed dates, as well as fate of struck and lost whales for all whaling villages were obtained from the AEWC. Biologists recorded similar information for most whales taken at Barrow, Gambell, Savoonga, and Kaktovik. Biologists also collected tissue samples and detailed morphometric data.

We estimated the approximate animal age and reproductive status based on several published criteria. Females with a total body length that is greater than 13.4 m in length are considered to be sexually mature; however, females shorter than this can be pregnant and females greater in length can be immature (George et al. 2004). Previously, we assumed sexual maturity at a total length of 14.2 m for females (Tarpley and Hillmann, 1999). Males with a total body length greater than 13 m are considered to be sexually mature (O’Hara et al., 2002).

RESULTS AND DISCUSSION

During 2012, 69 whales were struck during the Alaskan subsistence hunt. The total number of whales landed (n = 55) in 2012 was larger than the average number of whales landed over the previous 10 years (2002-2011: mean = 38.9 whales; SD = 7.1). Subsequently, the total number of whales struck was higher than the previous 10-year average (mean = 51.4; SD = 12.1).

Spring Hunting Conditions
A total of 21 bowheads was landed during the spring (Table 1). Hunting conditions during spring 2012 were generally favorable throughout northern and western Alaska.

Gambell and Savoonga, communities on Saint Lawrence Island in the Bering Sea, landed four and six whales, respectively, during the last half of April. After a very cold winter, the first half of April was marked by bad weather. The first pulse of bowheads to arrive at Saint Lawrence Island was observed in mid-April and coincided with favorable hunting conditions. Farther north the ice and weather conditions prevented hunters from Little Diomede and Kivalina from striking a whale.

Hunters at Wales have landed only nine bowheads between 1974 and 2011 (Suydam and George 2012) but were fortunate to land one on 22 April 2012. Point Hope, Point Lay, and Wainwright, on the coast of the Chukchi Sea, landed five, one, and four animals, respectively, between 13 April and 29 May.

At Barrow, the spring shorefast ice apron was much broader than usual at over 10 km in width. However, this did not interfere with the successful spring harvest of 14 whales between 22 April and 16 May.

Autumn Hunting Conditions
Eighteen whales were landed by four villages during the autumn migration (Barrow, Kaktovik, and Nuiqsut; Table 1). Kaktovik hunters landed three whales between 5 September and 2 October. A death in the community and windy conditions caused the hunt to be extended until early October. Hunting conditions were favorable for Nuiqsut where they completed their hunt by landing four whales from 5 to 12 September. At Barrow, nine bowheads were landed, between 1 and 6 October and one other on 19 October. Between 7 and 18 October there were strong westerly winds which prevented
any whale hunting at Barrow. Also, the general sense of the hunters was that whales were further offshore than usual. October also had record-setting warm temperatures so the ocean did not refreeze as it usually does in October.

**Struck and Lost and Hunting Efficiency**

Of the 14 whales that were struck and lost in 2012, one had an excellent chance of survival, two had a fair chance of survival, four had a poor chance of survival, five died and an estimated survival estimate was not recorded for two whales. The estimates of survival are primarily based on the Captain’s assessment but may be based on our assessment of the Captain’s description of the circumstances of the struck and lost whale (Table 2 and 3). This suggests the total hunting mortality for 2012 was 66 whales; i.e., 55 landed, and 11 whales that likely died after being struck and lost based on criteria in Suydam et al. (1995).

Overall efficiency of the hunt (#landed/#struck) in 2012 was 80%, which is similar to the average efficiency over the past 10 years (2002-2011: mean = 77%; SD = 7%). Since the mid-1970s, the efficiency of the harvest increased steadily until about the mid-1990s when it stabilized at about 80%. The increase was due to many factors, including enhanced communication (i.e., improved marine radio capabilities) among hunting crews, training of younger hunters, and improved weaponry (Suydam and George, 2012). However, the efficiency can vary substantially from year to year, primarily due to environmental conditions. For example, 2010 had a relatively low efficiency of 63% for a variety of reasons (see Suydam et al., 2011).

The success of the spring hunt is quite sensitive to variable environmental conditions (George et al., 2003). As such, efficiency varies between seasons and among years. The efficiency of the spring harvest is on average lower than the autumn harvest due to more demanding ice and weather conditions as well as struck whales escaping under the ice. In 2010, the overall efficiency of the spring hunt was quite low at 52%. However, in 2011, the efficiency of the spring hunt improved to 69% despite difficult ice conditions. The efficiency in 2012 was again relatively high at 71%.

The autumn hunts were successful and efficient (100%) in 2012. Twenty whales were landed and none were lost. Autumn hunts typically occur in more open water, thus sea ice is less of an influence on success. However, high wind speeds during the open water period in the autumn can make hunting opportunities extremely difficult (George et al., 2003). As climate change causes a greater and longer period of retreat of sea ice, the increased fetch contributes to larger swells that even persist after strong winds have abated. The overall hunting period has increased in recent years due to sea ice retreat, which possibly offsets inclement weather resulting in poor hunting conditions. For instance, a weather summary for October 2012 (Barrow) noted: “The mean value was 27.5°F, an astounding positive deviation of 10.3°F above the normal of 17.2°F. This was the result of temperatures that stayed decidedly above normal for nearly the whole month.” (http://climate.gi.alaska.edu).

**Sex and Maturity**

Twenty four (45%) of the landed whales of known sex (n = 53) were males. The longest male was 16.7 m and the shortest was 7.7 m. Based on a length of >13 m (O’Hara et al., 2002), seven males were presumably sexually mature. Confirmation of reproductive status of the whales is pending results of histological and hormonal analyses from a subset of these whales.

Twenty-nine (55%) of the landed whales of known sex (n = 53) were females. The longest female was 17.7 m and the shortest was 7.9 m. Based on a length > 13.4 m (George et al., 2004), six of the females were estimated to be sexually mature, five of which were examined closely. All five (100%) of those whales were pregnant. While the sample size is low this suggests a high pregnancy rate in 2012 compared with other years. In 2011, for instance, two of seven (29%) presumably mature females were pregnant which is consistent with the long-term average of about 33% (George et al., 2004; George et al., 2011). A 13.6 m female landed at Savoonga in the spring was pregnant with a 3.8 m female fetus. The other pregnant whales were landed in the autumn including: a 14.3 m female at Kaktovik with a 1.5 m fetus; a 16.3 m female landed at Gambell with a 2.4 m fetus; and two females (15.5 and 17.7 m) landed at Savoonga were pregnant with a 2.2 m female fetus and a 3.2 m male fetus (respectively).
The sex of two harvested bowhead whales was not determined. DNA test results to determine the gender of those whales are pending.

ACKNOWLEDGEMENTS

We thank the Alaska Eskimo Whaling Commission and local hunters for providing data on landed and struck but lost bowhead whales. We especially thank the Captains’ associations and hunters from Barrow, Saint Lawrence Island, and Kaktovik for their support and providing us access to their whales for examinations and sampling. Billy Adams, Teresa Aiken, Ross Burgener, Tony Bissen, Christian Christman, Sarah Coburn, Jenny Evans, Deb Green, Christina Hammock, Qaiyaan Harcharek, Jason Herreman, Lara Horstmann, Allen Kerner, Ryan Klimstra, Marty Martinson, George Noongwook, Emma Pokon, Pete Sformo, Todd Sformo, Leandra de Sousa, Kate Stafford, Hans Thewissen, Barb Tudor, and others assisted with data and sample collection in Barrow. Dolores Vinas, Molly Spicer, Janell Kaleak, Lucia Johnston, Bobby Sarren, Ross Burgener, and Dave Ramey provided logistical support in Barrow. The North Slope Borough and the National Oceanic and Atmospheric Administration provided financial support. Finally we thank Charlotte E. Brower (Mayor of the North Slope Borough) and Taqulik Hepa (Director of the North Slope Borough Department of Wildlife Management) for their encouragement and support.
